

PHASE 4 – PROJECT PLANNING

Script-Controlled ACL – Restrict Record Access Based on Field Value

1. Project Planning Overview

The project is planned to implement a Script-Controlled Access Control List (ACL) in ServiceNow. The main purpose of the project is to restrict access to student records based on the user's role and the branch value of the record.

The project is planned in a step-by-step manner, starting from user and role creation, followed by the creation of the Student Records table, adding branch-based records, configuring ACLs, applying access control scripts, and finally verifying the access permissions using different users.

2. Project Implementation Plan

The project implementation is planned through the following activities:

Step 1 – Create Users and Roles

Create the required users and assign appropriate roles for testing different access permissions.

Step 2 – Create Student Records Table

Create the Student Records table in ServiceNow to store the records that need to be protected.

Step 3 – Add Branch Values

Create student records with different branch values such as ECE, EEE, and CSE. These branch values are used by the ACL script for access control.

Step 4 – Configure Read ACL

Create a Read ACL to control which users can view the student records. The ACL script checks the user's role and the branch value before allowing access.

Step 5 – Configure Write ACL

Create a Write ACL to control modification of student records. Only users who satisfy the required access conditions should be allowed to modify the records.

Step 6 – Configure Create ACL

Create a Create ACL to control the creation of new student records. The ACL verifies whether the user has the required permission to create records.

Step 7 – Configure Delete ACL

Create a Delete ACL to control the deletion of student records. Only users with the required permission should be allowed to delete records.

Step 8 – Verify Access Permissions

Test the configured ACLs using different users and roles. The access behavior is checked for different branch records to verify that authorized users receive access and unauthorized users are restricted.

3. Project Workflow

4. Access Control Planning

The access control is planned using two main conditions:

User Role
+
Branch Value

The ACL script checks these conditions before allowing the requested operation.

For example, an authorized EEE user should be able to access the permitted EEE records, while access to restricted records should be denied.

Administrators are planned to have full access to the Student Records table.

5. ACL Planning

The following ACLs are planned for the project:

ACL	Planned Function
Read ACL	Control viewing of student records
Write ACL	Control modification of student records
Create ACL	Control creation of student records
Delete ACL	Control deletion of student records

Each ACL is planned to verify the required role and branch-based conditions.

6. Testing Plan

After implementing the ACLs, the project will be tested using different users and roles.

The following conditions will be verified:

- Authorized user accessing permitted records.
- User accessing a restricted branch record.
- Administrator accessing records.
- User attempting to modify a restricted record.
- User attempting to create a record.
- User attempting to delete a record.

The purpose of testing is to ensure that the configured ACLs correctly allow or deny access.

7. Project Timeline

8. Expected Planning Outcome

The planned implementation should result in a ServiceNow access-control system where student records are protected using Script-Controlled ACLs.

The system should:

- Control access based on user roles.
- Check the branch value of records.
- Control Read, Write, Create, and Delete operations.
- Allow authorized users to access permitted records.
- Restrict unauthorized access.
- Provide administrators with full access.

9. Conclusion

The project planning provides a structured sequence for implementing and verifying Script-Controlled ACLs in ServiceNow. By following the planned activities, the project can systematically configure users, roles, student records, ACLs, and access conditions. The final testing verifies whether the required record-level access restrictions work correctly.
